Near Rings And Near Fields

Most topics in near-ring and near-field theory are treated here, along with an extensive introduction to the theory. There are two invited lectures: Non-Commutative Geometry, Near-Rings and Near-Fields" which indicates the relevance of near-rings and near-fields for geometry, whilePseudo-Finite Near-Fields" shows the impressive power of model theoretic methods.

Near-Rings and Near-Fields, Volume 137 - 1st Edition

Near-Rings and Near-Fields opens with three invited lectures on different aspects of the history of near-ring theory. These are followed by 26 papers reflecting the diversity of the subject in regard to geometry, topological groups, automata, coding theory and probability, as well as the purely algebraic structure theory of near-rings.

Rings do not have to be commutative. If a ring is commutative, then we say the ring is a commutative ring. Rings do not need to have a multiplicative inverse. From this definition we can say that all fields are rings since every component of the definition of a ring is also in the definition of a field. Example 4. Explain why \mathbb{Z} is a ...

Algebraic Structures - Fields, Rings, and Groups - Mathonline

In mathematics, a near-field is an algebraic structure similar to a division ring, except that it has only one of the two distributive laws. Alternatively, a near-field is a near-ring in which there is a multiplicative identity, and every non-zero element has a multiplicative inverse .

Rings - fields

Actually, the first near-rings considered were near-fields, near-rings in which forms a group. In 1905, L. E. Dickson constructed the first proper near-fields by "distorting" the multiplication in a field. These types of near-fields are now called Dickson near-fields. Two years later, Veblen and Wedderburn used near-fields to coordinatize geometric planes.

Those may be called semirings of characteristic one (the only ring of characteristic one is the trivial field). A near-ring is a ring-like structure where the additive group is not necessarily abelian (i.e., addition needn't be commutative). Multiplication must still be associative but distributivity may not hold on both sides.

SEMIENDOMORPHISMS OF SIMPLE NEAR-RINGS KIRBY C SMITH AND LEON VAN WYK (Communicated by Maurice Auslander) Abstract. Let N be a finite simple centralizer near-ring that is not an ex-ceptional near-field. A semiendomorphism of N is a map f from N into N such that $(a + b)^f = a^f + b^f$, $(aba)^f = a^f b^f a^f$, and $1^f = 1$ for all $a, b \in N$.
