Perl has several different functions that are useful for flow control, the most basic of which is for. When you use the for function, you specify a variable that will be used for the loop index, and a list of values to loop over. Inside a pair of curly brackets, you put any code you want to run during the loop:

Any Perl/Tk application starts by creating the Tk MainWindow. You then create items inside the MainWindow, and/or create new windows called Toplevel s that also contain child items, before starting the MainLoop, which is the last logical statment in your program. You can also create more items and windows while you're running, using callbacks.

Before installing Apache and mod_perl, you usually have to become root so that the files can be installed in a protected area. A user who does not have root access, however, can still install all files under their home directory. The proper approach is to build Apache in an unprivileged location and then only use root access to install it.
