SystemVerilog Verification Using UVM - Synopsis

UVM is a methodology for the functional verification of digital hardware, primarily using simulation. The hardware or system to be verified would typically be described using Verilog, SystemVerilog, VHDL or SystemC at any appropriate abstraction level. This could be behavioral, register transfer level, or gate level.

the IEEE1800.1 class-based verification library and reuse methodology for SystemVerilog. The UVM class library provides the basic building blocks for creating verification data and components. The UVM methodology enables engineers to quickly develop powerful, reusable, and scalable object-oriented verification environments.

SystemVerilog Accelerated Verification with UVM

Users writing testbenches with the SystemVerilog Universal Verification Methodology (UVM) or any kind of class-based methodology can learn from these techniques. Design patterns are optimized, reusable solutions to commonly occurring programming problems.

Design patterns in SystemVerilog OOP for UVM verification ...

Universal Verification Methodology (UVM) is a standard to enable faster development and reuse of verification environments and verification IP (VIP) throughout the industry. It is a set of class libraries defined using the syntax and semantics of SystemVerilog (IEEE 1800) and is now an IEEE standard. The main idea behind UVM is to help companies develop modular, reusable, and scalable testbench structures by providing an API framework that can be deployed across multiple projects.
